

CH12 – INTRODUCTION TO 3D

GEOMETRY

Exercise 12.1, Page No. 271

1. A point is on the x-axis. What are its y-coordinate and z-coordinates?

Solution:

If a point is on the x-axis, then the coordinates of y and z are 0.

So the point is $(x, 0, 0)$.

2. A point is in the XZ-plane. What can you say about its y-coordinate?

Solution:

If a point is in the XZ plane, then its y-co-ordinate is 0.

3. Name the octants in which the following points lie: $(1, 2, 3)$, $(4, -2, 3)$, $(4, -2, -5)$, $(4, 2, -5)$, $(-4, 2, -5)$, $(-4, 2, 5)$, $(-3, -1, 6)$, $(2, -4, -7)$.

Solution:

Here is the table which represents the octants:

Octants	I	II	III	IV	V	VI	VII	VIII
x	+	-	-	+	+	-	-	+
y	+	+	-	-	+	+	-	-
z	+	+	+	+	-	-	-	-

(i) $(1, 2, 3)$

Here, x is positive, y is positive, and z is positive.

So, it lies in the I octant.

(ii) $(4, -2, 3)$

Here, x is positive, y is negative, and z is positive.

So, it lies in the IV octant.

(iii) $(4, -2, -5)$

Here, x is positive, y is negative, and z is negative.

So, it lies in the VIII octant.

(iv) $(4, 2, -5)$

Here, x is positive, y is positive, and z is negative.

So, it lies in the V octant.

(v) $(-4, 2, -5)$

Here, x is negative, y is positive, and z is negative.

So, it lies in VI octant.

(vi) $(-4, 2, 5)$

Here, x is negative, y is positive, and z is positive.

So, it lies in the II octant.

(vii) $(-3, -1, 6)$

Here, x is negative, y is negative, and z is positive.

So, it lies in the III octant.

(viii) $(2, -4, -7)$

Here, x is positive, y is negative, and z is negative.

So, it lies in the VIII octant.

4. Fill in the blanks:

(i) The x-axis and y-axis, taken together, determine a plane known as _____.

(ii) The coordinates of points in the XY-plane are of the form _____.

(iii) Coordinate planes divide the space into _____ octants.

Solution:

(i) The x-axis and y-axis, taken together, determine a plane known as XY Plane.

(ii) The coordinates of points in the XY-plane are of the form $(x, y, 0)$.

(iii) Coordinate planes divide the space into eight octants.

Exercise 12.2 Page No. 273

1. Find the distance between the following pairs of points:

(i) $(2, 3, 5)$ and $(4, 3, 1)$

(ii) $(-3, 7, 2)$ and $(2, 4, -1)$

(iii) $(-1, 3, -4)$ and $(1, -3, 4)$

(iv) $(2, -1, 3)$ and $(-2, 1, 3)$

Solution:

(i) $(2, 3, 5)$ and $(4, 3, 1)$

Let P be $(2, 3, 5)$ and Q be $(4, 3, 1)$

By using the formula,

$$\text{Distance PQ} = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$$

So, here

$$x_1 = 2, y_1 = 3, z_1 = 5$$

$$x_2 = 4, y_2 = 3, z_2 = 1$$

$$\text{Distance PQ} = \sqrt{[(4 - 2)^2 + (3 - 3)^2 + (1 - 5)^2]}$$

$$= \sqrt{[(2)^2 + 0^2 + (-4)^2]}$$

$$= \sqrt{[4 + 0 + 16]}$$

$$= \sqrt{20}$$

$$= 2\sqrt{5}$$

∴ The required distance is $2\sqrt{5}$ units.

(ii) $(-3, 7, 2)$ and $(2, 4, -1)$

Let P be $(-3, 7, 2)$ and Q be $(2, 4, -1)$

By using the formula,

$$\text{Distance PQ} = \sqrt{[(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2]}$$

So, here

$$x_1 = -3, y_1 = 7, z_1 = 2$$

$$x_2 = 2, y_2 = 4, z_2 = -1$$

$$\text{Distance PQ} = \sqrt{[(2 - (-3))^2 + (4 - 7)^2 + (-1 - 2)^2]}$$

$$= \sqrt{[(5)^2 + (-3)^2 + (-3)^2]}$$

$$= \sqrt{[25 + 9 + 9]}$$

$$= \sqrt{43}$$

∴ The required distance is $\sqrt{43}$ units.

(iii) $(-1, 3, -4)$ and $(1, -3, 4)$

Let P be $(-1, 3, -4)$ and Q be $(1, -3, 4)$

By using the formula,

$$\text{Distance PQ} = \sqrt{[(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2]}$$

So here,

$$x_1 = -1, y_1 = 3, z_1 = -4$$

$$x_2 = 1, y_2 = -3, z_2 = 4$$

$$\text{Distance PQ} = \sqrt{[(1 - (-1))^2 + (-3 - 3)^2 + (4 - (-4))^2]}$$

$$= \sqrt{[(2)^2 + (-6)^2 + (8)^2]}$$

$$= \sqrt{[4 + 36 + 64]}$$

$$= \sqrt{104}$$

$$= 2\sqrt{26}$$

∴ The required distance is $2\sqrt{26}$ units.

(iv) $(2, -1, 3)$ and $(-2, 1, 3)$

Let P be $(2, -1, 3)$ and Q be $(-2, 1, 3)$

By using the formula,

$$\text{Distance PQ} = \sqrt{[(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2]}$$

So here,

$$x_1 = 2, y_1 = -1, z_1 = 3$$

$$x_2 = -2, y_2 = 1, z_2 = 3$$

$$\text{Distance PQ} = \sqrt{(-2 - 2)^2 + (1 - (-1))^2 + (3 - 3)^2}$$

$$= \sqrt{(-4)^2 + (2)^2 + (0)^2}$$

$$= \sqrt{16 + 4 + 0}$$

$$= \sqrt{20}$$

$$= 2\sqrt{5}$$

∴ The required distance is $2\sqrt{5}$ units.

2. Show that the points $(-2, 3, 5)$, $(1, 2, 3)$ and $(7, 0, -1)$ are collinear.

Solution:

If three points are collinear, then they lie on the same line.

First, let us calculate the distance between the 3 points

i.e., PQ, QR and PR

Calculating PQ

$$P \equiv (-2, 3, 5) \text{ and } Q \equiv (1, 2, 3)$$

By using the formula,

$$\text{Distance PQ} = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$$

So, here

$$x_1 = -2, y_1 = 3, z_1 = 5$$

$$x_2 = 1, y_2 = 2, z_2 = 3$$

$$\text{Distance PQ} = \sqrt{(1 - (-2))^2 + (2 - 3)^2 + (3 - 5)^2}$$

$$= \sqrt{(3)^2 + (-1)^2 + (-2)^2}$$

$$= \sqrt{9 + 1 + 4}$$

$$= \sqrt{14}$$

Calculating QR

$$Q \equiv (1, 2, 3) \text{ and } R \equiv (7, 0, -1)$$

By using the formula,

$$\text{Distance QR} = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$$

So, here

$$x_1 = 1, y_1 = 2, z_1 = 3$$

$$x_2 = 7, y_2 = 0, z_2 = -1$$

$$\text{Distance QR} = \sqrt{(7 - 1)^2 + (0 - 2)^2 + (-1 - 3)^2}$$

$$= \sqrt{(6)^2 + (-2)^2 + (-4)^2}$$

$$= \sqrt{36 + 4 + 16}$$

$$= \sqrt{56}$$

$$= 2\sqrt{14}$$

Calculating PR

$P \equiv (-2, 3, 5)$ and $R \equiv (7, 0, -1)$

By using the formula,

$$\text{Distance PR} = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$$

So here,

$$x_1 = -2, y_1 = 3, z_1 = 5$$

$$x_2 = 7, y_2 = 0, z_2 = -1$$

$$\text{Distance PR} = \sqrt{(7 - (-2))^2 + (0 - 3)^2 + (-1 - 5)^2}$$

$$= \sqrt{(9)^2 + (-3)^2 + (-6)^2}$$

$$= \sqrt{81 + 9 + 36}$$

$$= \sqrt{126}$$

$$= 3\sqrt{14}$$

$$\text{Thus, } PQ = \sqrt{14}, QR = 2\sqrt{14} \text{ and } PR = 3\sqrt{14}$$

$$\text{So, } PQ + QR = \sqrt{14} + 2\sqrt{14}$$

$$= 3\sqrt{14}$$

$$= PR$$

\therefore The points P, Q and R are collinear.

3. Verify the following:

(i) $(0, 7, -10)$, $(1, 6, -6)$, and $(4, 9, -6)$ are the vertices of an isosceles triangle.

(ii) $(0, 7, 10)$, $(-1, 6, 6)$, and $(-4, 9, 6)$ are the vertices of a right-angled triangle.

(iii) $(-1, 2, 1)$, $(1, -2, 5)$, $(4, -7, 8)$, and $(2, -3, 4)$ are the vertices of a parallelogram.

Solution:

(i) $(0, 7, -10)$, $(1, 6, -6)$, and $(4, 9, -6)$ are the vertices of an isosceles triangle.

Let us consider the points,

$$P(0, 7, -10), Q(1, 6, -6) \text{ and } R(4, 9, -6)$$

If any 2 sides are equal, it will be an isosceles triangle

So, first, let us calculate the distance of PQ, QR

Calculating PQ

$$P \equiv (0, 7, -10) \text{ and } Q \equiv (1, 6, -6)$$

By using the formula,

$$\text{Distance PQ} = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$$

So, here,

$$x_1 = 0, y_1 = 7, z_1 = -10$$

$$x_2 = 1, y_2 = 6, z_2 = -6$$

$$\text{Distance PQ} = \sqrt{(1 - 0)^2 + (6 - 7)^2 + (-6 - (-10))^2}$$

$$\begin{aligned} &= \sqrt{[(1)^2 + (-1)^2 + (4)^2]} \\ &= \sqrt{[1 + 1 + 16]} \\ &= \sqrt{18} \end{aligned}$$

Calculating QR

$$Q \equiv (1, 6, -6) \text{ and } R \equiv (4, 9, -6)$$

By using the formula,

$$\text{Distance QR} = \sqrt{[(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2]}$$

So, here

$$x_1 = 1, y_1 = 6, z_1 = -6$$

$$x_2 = 4, y_2 = 9, z_2 = -6$$

$$\begin{aligned} \text{Distance QR} &= \sqrt{[(4 - 1)^2 + (9 - 6)^2 + (-6 - (-6))^2]} \\ &= \sqrt{[(3)^2 + (3)^2 + (-6 + 6)^2]} \\ &= \sqrt{[9 + 9 + 0]} \\ &= \sqrt{18} \end{aligned}$$

Hence, PQ = QR

$$18 = 18$$

2 sides are equal

\therefore PQR is an isosceles triangle.

(ii) (0, 7, 10), (-1, 6, 6), and (-4, 9, 6) are the vertices of a right-angled triangle.

Let the points be

$$P(0, 7, 10), Q(-1, 6, 6) \text{ \& } R(-4, 9, 6)$$

First, let us calculate the distance of PQ, QR and PR

Calculating PQ

$$P \equiv (0, 7, 10) \text{ and } Q \equiv (-1, 6, 6)$$

By using the formula,

$$\text{Distance PQ} = \sqrt{[(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2]}$$

So here,

$$x_1 = 0, y_1 = 7, z_1 = 10$$

$$x_2 = -1, y_2 = 6, z_2 = 6$$

$$\begin{aligned} \text{Distance PQ} &= \sqrt{[(-1 - 0)^2 + (6 - 7)^2 + (6 - 10)^2]} \\ &= \sqrt{[(-1)^2 + (-1)^2 + (-4)^2]} \\ &= \sqrt{[1 + 1 + 16]} \\ &= \sqrt{18} \end{aligned}$$

Calculating QR

$$Q \equiv (1, 6, -6) \text{ and } R \equiv (4, 9, -6)$$

By using the formula,

$$\text{Distance QR} = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$$

So, here

$$x_1 = 1, y_1 = 6, z_1 = -6$$

$$x_2 = 4, y_2 = 9, z_2 = -6$$

$$\text{Distance QR} = \sqrt{(4 - 1)^2 + (9 - 6)^2 + (-6 - (-6))^2}$$

$$= \sqrt{(3)^2 + (3)^2 + (-6 + 6)^2}$$

$$= \sqrt{9 + 9 + 0}$$

$$= \sqrt{18}$$

Calculating PR

$$P \equiv (0, 7, 10) \text{ and } R \equiv (-4, 9, 6)$$

By using the formula,

$$\text{Distance PR} = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$$

So, here

$$x_1 = 0, y_1 = 7, z_1 = 10$$

$$x_2 = -4, y_2 = 9, z_2 = 6$$

$$\text{Distance PR} = \sqrt{(-4 - 0)^2 + (9 - 7)^2 + (6 - 10)^2}$$

$$= \sqrt{(-4)^2 + (2)^2 + (-4)^2}$$

$$= \sqrt{16 + 4 + 16}$$

$$= \sqrt{36}$$

Now,

$$PQ^2 + QR^2 = 18 + 18$$

$$= 36$$

$$= PR^2$$

By using the converse of Pythagoras theorem,

∴ The given vertices P, Q & R are the vertices of a right-angled triangle at Q.

(iii) $(-1, 2, 1)$, $(1, -2, 5)$, $(4, -7, 8)$, and $(2, -3, 4)$ are the vertices of a parallelogram.

Let the points: $A(-1, 2, 1)$, $B(1, -2, 5)$, $C(4, -7, 8)$ & $D(2, -3, 4)$

ABCD can be vertices of parallelogram only if opposite sides are equal.

i.e., $AB = CD$ and $BC = AD$

First, let us calculate the distance

Calculating AB

$$A \equiv (-1, 2, 1) \text{ and } B \equiv (1, -2, 5)$$

By using the formula,

$$\text{Distance AB} = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$$

So, here

$$x_1 = -1, y_1 = 2, z_1 = 1$$

$$x_2 = 1, y_2 = -2, z_2 = 5$$

$$\text{Distance AB} = \sqrt{[(1 - (-1))^2 + (-2 - 2)^2 + (5 - 1)^2]}$$

$$= \sqrt{[(2)^2 + (-4)^2 + (4)^2]}$$

$$= \sqrt{[4 + 16 + 16]}$$

$$= \sqrt{36}$$

$$= 6$$

Calculating BC

$$B \equiv (1, -2, 5) \text{ and } C \equiv (4, -7, 8)$$

By using the formula,

$$\text{Distance BC} = \sqrt{[(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2]}$$

So, here

$$x_1 = 1, y_1 = -2, z_1 = 5$$

$$x_2 = 4, y_2 = -7, z_2 = 8$$

$$\text{Distance BC} = \sqrt{[(4 - 1)^2 + (-7 - (-2))^2 + (8 - 5)^2]}$$

$$= \sqrt{[(3)^2 + (-5)^2 + (3)^2]}$$

$$= \sqrt{[9 + 25 + 9]}$$

$$= \sqrt{43}$$

Calculating CD

$$C \equiv (4, -7, 8) \text{ and } D \equiv (2, -3, 4)$$

By using the formula,

$$\text{Distance CD} = \sqrt{[(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2]}$$

So here,

$$x_1 = 4, y_1 = -7, z_1 = 8$$

$$x_2 = 2, y_2 = -3, z_2 = 4$$

$$\text{Distance CD} = \sqrt{[(2 - 4)^2 + (-3 - (-7))^2 + (4 - 8)^2]}$$

$$= \sqrt{[(-2)^2 + (4)^2 + (-4)^2]}$$

$$= \sqrt{[4 + 16 + 16]}$$

$$= \sqrt{36}$$

$$= 6$$

Calculating DA

$$D \equiv (2, -3, 4) \text{ and } A \equiv (-1, 2, 1)$$

By using the formula,

$$\text{Distance DA} = \sqrt{[(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2]}$$

So, here

$$x_1 = 2, y_1 = -3, z_1 = 4$$

$$x_2 = -1, y_2 = 2, z_2 = 1$$

$$\text{Distance DA} = \sqrt{[(-1 - 2)^2 + (2 - (-3))^2 + (1 - 4)^2]}$$

$$\begin{aligned} &= \sqrt{(-3)^2 + (5)^2 + (-3)^2} \\ &= \sqrt{9 + 25 + 9} \\ &= \sqrt{43} \end{aligned}$$

Since $AB = CD$ and $BC = DA$ (given),

In ABCD, both pairs of opposite sides are equal.

\therefore ABCD is a parallelogram.

4. Find the equation of the set of points which are equidistant from the points (1, 2, 3) and (3, 2, -1).

Solution:

Let A (1, 2, 3) & B (3, 2, -1)

Let point P be (x, y, z)

Since it is given that point P(x, y, z) is equal distance from point A(1, 2, 3) & B(3, 2, -1)

i.e. $PA = PB$

First, let us calculate

Calculating PA

$P \equiv (x, y, z)$ and $A \equiv (1, 2, 3)$

By using the formula,

$$\text{Distance PA} = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$$

So, here

$$x_1 = x, y_1 = y, z_1 = z$$

$$x_2 = 1, y_2 = 2, z_2 = 3$$

$$\text{Distance PA} = \sqrt{(1 - x)^2 + (2 - y)^2 + (3 - z)^2}$$

Calculating PB

$P \equiv (x, y, z)$ and $B \equiv (3, 2, -1)$

By using the formula,

$$\text{Distance PB} = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$$

So, here

$$x_1 = x, y_1 = y, z_1 = z$$

$$x_2 = 3, y_2 = 2, z_2 = -1$$

$$\text{Distance PB} = \sqrt{(3 - x)^2 + (2 - y)^2 + (-1 - z)^2}$$

Since $PA = PB$

Square on both sides, we get

$$PA^2 = PB^2$$

$$(1 - x)^2 + (2 - y)^2 + (3 - z)^2 = (3 - x)^2 + (2 - y)^2 + (-1 - z)^2$$

$$(1 + x^2 - 2x) + (4 + y^2 - 4y) + (9 + z^2 - 6z)$$

$$(9 + x^2 - 6x) + (4 + y^2 - 4y) + (1 + z^2 + 2z)$$

$$-2x - 4y - 6z + 14 = -6x - 4y + 2z + 14$$

$$4x - 8z = 0$$

$$x - 2z = 0$$

∴ The required equation is $x - 2z = 0$.

5. Find the equation of the set of points P, the sum of whose distances from A(4, 0, 0) and B(-4, 0, 0) is equal to 10.

Solution:

Let A(4, 0, 0) & B(-4, 0, 0)

Let the coordinates of point P be (x, y, z)

Calculating PA

P ≡ (x, y, z) and A ≡ (4, 0, 0)

By using the formula,

$$\text{Distance PA} = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$$

So, here

$$x_1 = x, y_1 = y, z_1 = z$$

$$x_2 = 4, y_2 = 0, z_2 = 0$$

$$\text{Distance PA} = \sqrt{(4 - x)^2 + (0 - y)^2 + (0 - z)^2}$$

Calculating PB,

P ≡ (x, y, z) and B ≡ (-4, 0, 0)

By using the formula,

$$\text{Distance PB} = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$$

So here,

$$x_1 = x, y_1 = y, z_1 = z$$

$$x_2 = -4, y_2 = 0, z_2 = 0$$

$$\text{Distance PB} = \sqrt{(-4 - x)^2 + (0 - y)^2 + (0 - z)^2}$$

It is given that,

$$\text{PA} + \text{PB} = 10$$

$$\text{PA} = 10 - \text{PB}$$

Square on both sides, we get

$$\text{PA}^2 = (10 - \text{PB})^2$$

$$\text{PA}^2 = 100 + \text{PB}^2 - 20 \text{PB}$$

$$(4 - x)^2 + (0 - y)^2 + (0 - z)^2$$

$$100 + (-4 - x)^2 + (0 - y)^2 + (0 - z)^2 - 20 \text{PB}$$

$$(16 + x^2 - 8x) + (y^2) + (z^2)$$

$$100 + (16 + x^2 + 8x) + (y^2) + (z^2) - 20 \text{PB}$$

$$20 \text{PB} = 16x + 100$$

$$5 \text{PB} = (4x + 25)$$

Square on both sides again, we get

$$25 PB^2 = 16x^2 + 200x + 625$$

$$25 [(-4 - x)^2 + (0 - y)^2 + (0 - z)^2] = 16x^2 + 200x + 625$$

$$25 [x^2 + y^2 + z^2 + 8x + 16] = 16x^2 + 200x + 625$$

$$25x^2 + 25y^2 + 25z^2 + 200x + 400 = 16x^2 + 200x + 625$$

$$9x^2 + 25y^2 + 25z^2 - 225 = 0$$

∴ The required equation is $9x^2 + 25y^2 + 25z^2 - 225 = 0$.

Exercise 12.3 Page No. 277

1. Find the coordinates of the point which divides the line segment joining the points $(-2, 3, 5)$ and $(1, -4, 6)$ in the ratio (i) 2:3 internally, (ii) 2:3 externally.

Solution:

Let the line segment joining the points $P(-2, 3, 5)$ and $Q(1, -4, 6)$ be PQ .

(i) 2:3 internally

By using the section formula,

We know that the coordinates of the point R , which divides the line segment joining two points $P(x_1, y_1, z_1)$ and $Q(x_2, y_2, z_2)$ internally in the ratio $m:n$, is given by:

$$\left(\frac{mx_2 + nx_1}{m+n}, \frac{my_2 + ny_1}{m+n}, \frac{mz_2 + nz_1}{m+n} \right)$$

Upon comparing, we have

$$x_1 = -2, y_1 = 3, z_1 = 5;$$

$$x_2 = 1, y_2 = -4, z_2 = 6 \text{ and}$$

$$m = 2, n = 3$$

So, the coordinates of the point which divide the line segment joining the points $P(-2, 3, 5)$ and $Q(1, -4, 6)$ in the ratio 2:3 internally is given by:

$$\left(\frac{2 \times 1 + 3 \times (-2)}{2+3}, \frac{2 \times (-4) + 3 \times 3}{2+3}, \frac{2 \times 6 + 3 \times 5}{2+3} \right)$$

$$= \left(\frac{2-6}{5}, \frac{-8+9}{5}, \frac{12+15}{5} \right)$$

$$= \left(\frac{-4}{5}, \frac{1}{5}, \frac{27}{5} \right)$$

Hence, the coordinates of the point which divides the line segment joining the points $(-2, 3, 5)$ and $(1, -4, 6)$ is $(-4/5, 1/5, 27/5)$.

(ii) 2:3 externally

By using the section formula,

We know that the coordinates of the point R, which divides the line segment joining two points P (x_1, y_1, z_1) and Q (x_2, y_2, z_2) externally in the ratio $m:n$, is given by:

$$\left(\frac{mx_2 - nx_1}{m - n}, \frac{my_2 - ny_1}{m - n}, \frac{mz_2 - nz_1}{m - n} \right)$$

Upon comparing, we have

$$x_1 = -2, y_1 = 3, z_1 = 5;$$

$$x_2 = 1, y_2 = -4, z_2 = 6 \text{ and}$$

$$m = 2, n = 3$$

So, the coordinates of the point which divide the line segment joining the points P (-2, 3, 5) and Q (1, -4, 6) in the ratio 2:3 externally is given by:

$$\begin{aligned} & \left(\frac{2 \times 1 - 3 \times (-2)}{2 - 3}, \frac{2 \times (-4) - 3 \times 3}{2 - 3}, \frac{2 \times 6 - 3 \times 5}{2 - 3} \right) \\ &= \left(\frac{2 - (-6)}{-1}, \frac{-8 - 9}{-1}, \frac{12 - 15}{-1} \right) \\ &= \left(\frac{8}{-1}, \frac{-17}{-1}, \frac{-3}{-1} \right) \\ &= (-8, 17, 3) \end{aligned}$$

\therefore The coordinates of the point which divides the line segment joining the points (-2, 3, 5) and (1, -4, 6) is (-8, 17, 3).

2. Given that P (3, 2, -4), Q (5, 4, -6) and R (9, 8, -10) are collinear. Find the ratio in which Q divides PR.

Solution:

Let us consider Q divides PR in the ratio $k:1$.

By using the section formula,

We know that the coordinates of the point R, which divides the line segment joining two points P (x_1, y_1, z_1) and Q (x_2, y_2, z_2) internally in the ratio $m:n$, is given by:

$$\left(\frac{mx_2 + nx_1}{m + n}, \frac{my_2 + ny_1}{m + n}, \frac{mz_2 + nz_1}{m + n} \right)$$

Upon comparing, we have,

$$x_1 = 3, y_1 = 2, z_1 = -4;$$

$$x_2 = 9, y_2 = 8, z_2 = -10 \text{ and}$$

$$m = k, n = 1$$

So, we have

$$\left(\frac{9k+3}{k+1}, \frac{8k+2}{k+1}, \frac{-10k-4}{k+1} \right) = (5, 4, -6)$$

$$\frac{9k+3}{k+1} = 5, \frac{8k+2}{k+1} = 4, \frac{-10k-4}{k+1} = -6$$

$$9k+3 = 5(k+1)$$

$$9k+3 = 5k+5$$

$$9k-5k = 5-3$$

$$4k = 2$$

$$k = 2/4$$

$$= 1/2$$

Hence, the ratio in which Q divides PR is 1:2.

3. Find the ratio in which the YZ-plane divides the line segment formed by joining the points (-2, 4, 7) and (3, -5, 8).

Solution:

Let the line segment formed by joining the points P (-2, 4, 7) and Q (3, -5, 8) be PQ.

We know that any point on the YZ-plane is of the form (0, y, z).

So, let R (0, y, z) divides the line segment PQ in the ratio k:1.

Then,

Upon comparing, we have,

$$x_1 = -2, y_1 = 4, z_1 = 7;$$

$$x_2 = 3, y_2 = -5, z_2 = 8 \text{ and}$$

$$m = k, n = 1$$

By using the section formula,

We know that the coordinates of the point R, which divides the line segment joining two points P (x_1, y_1, z_1) and Q (x_2, y_2, z_2) internally in the ratio m:n, is given by:

$$\left(\frac{mx_2 + nx_1}{m+n}, \frac{my_2 + ny_1}{m+n}, \frac{mz_2 + nz_1}{m+n} \right)$$

So we have,

$$\left(\frac{3k-2}{k+1}, \frac{-5k+4}{k+1}, \frac{8k+7}{k+1} \right) = (0, y, z)$$

$$\frac{3k-2}{k+1} = 0$$

$$3k-2 = 0$$

$$3k = 2$$

$$k = 2/3$$

Hence, the ratio in which the YZ-plane divides the line segment formed by joining the points $(-2, 4, 7)$ and $(3, -5, 8)$ is 2:3.

4. Using the section formula, show that the points A $(2, -3, 4)$, B $(-1, 2, 1)$ and C $(0, 1/3, 2)$ are collinear.

Solution:

Let point P divides AB in the ratio $k:1$.

Upon comparing, we have,

$$x_1 = 2, y_1 = -3, z_1 = 4;$$

$$x_2 = -1, y_2 = 2, z_2 = 1 \text{ and}$$

$$m = k, n = 1$$

By using the section formula,

We know that the coordinates of the point R, which divides the line segment joining two points P (x_1, y_1, z_1) and Q (x_2, y_2, z_2) internally in the ratio $m:n$, is given by:

$$\left(\frac{mx_2 + nx_1}{m+n}, \frac{my_2 + ny_1}{m+n}, \frac{mz_2 + nz_1}{m+n} \right)$$

So we have,

$$\text{The coordinates of P} = \left(\frac{-k+2}{k+1}, \frac{2k-3}{k+1}, \frac{k+4}{k+1} \right)$$

Now, we check if, for some value of k , the point coincides with point C.

$$\text{Put } (-k+2)/(k+1) = 0$$

$$-k + 2 = 0$$

$$k = 2$$

$$\text{When } k = 2, \text{ then } (2k-3)/(k+1) = (2(2)-3)/(2+1)$$

$$= (4-3)/3$$

$$= 1/3$$

$$\text{And, } (k+4)/(k+1) = (2+4)/(2+1)$$

$$= 6/3$$

$$= 2$$

\therefore C $(0, 1/3, 2)$ is a point which divides AB in the ratio 2:1 and is the same as P.

Hence, A, B, and C are collinear.

5. Find the coordinates of the points which trisect the line segment joining the points P $(4, 2, -6)$ and Q $(10, -16, 6)$.

Solution:

Let A (x_1, y_1, z_1) and B (x_2, y_2, z_2) trisect the line segment joining the points P (4, 2, -6) and Q (10, -16, 6).

A divides the line segment PQ in the ratio 1:2.

Upon comparing, we have,

$$x_1 = 4, y_1 = 2, z_1 = -6;$$

$$x_2 = 10, y_2 = -16, z_2 = 6 \text{ and}$$

$$m = 1, n = 2$$

By using the section formula,

We know that the coordinates of the point R, which divides the line segment joining two points P (x_1, y_1, z_1) and Q (x_2, y_2, z_2) internally in the ratio $m:n$, is given by:

$$\left(\frac{mx_2 + nx_1}{m+n}, \frac{my_2 + ny_1}{m+n}, \frac{mz_2 + nz_1}{m+n} \right)$$

So, we have

$$\begin{aligned} \text{The coordinates of A} &= \left(\frac{1 \times 10 + 2 \times 4}{1+2}, \frac{1 \times (-16) + 2 \times 2}{1+2}, \frac{1 \times 6 + 2 \times (-6)}{1+2} \right) \\ &= \left(\frac{18}{3}, \frac{-12}{3}, \frac{-6}{3} \right) \\ &= (6, -4, -2) \end{aligned}$$

Similarly, we know that B divides the line segment PQ in the ratio 2:1.

Upon comparing, we have,

$$x_1 = 4, y_1 = 2, z_1 = -6;$$

$$x_2 = 10, y_2 = -16, z_2 = 6 \text{ and}$$

$$m = 2, n = 1$$

By using the section formula,

We know that the coordinates of the point R, which divides the line segment joining two points P (x_1, y_1, z_1) and Q (x_2, y_2, z_2) internally in the ratio $m:n$, is given by:

$$\left(\frac{mx_2 + nx_1}{m+n}, \frac{my_2 + ny_1}{m+n}, \frac{mz_2 + nz_1}{m+n} \right)$$

So, we have

$$\begin{aligned} \text{The coordinates of B} &= \left(\frac{2 \times 10 + 1 \times 4}{2+1}, \frac{2 \times (-16) + 1 \times 2}{2+1}, \frac{2 \times 6 + 1 \times (-6)}{2+1} \right) \\ &= \left(\frac{24}{3}, \frac{-30}{3}, \frac{6}{3} \right) \\ &= (8, -10, 2) \end{aligned}$$

\therefore The coordinates of the points which trisect the line segment joining the points P (4, 2, -6) and Q (10, -16, 6) are (6, -4, -2) and (8, -10, 2).

Miscellaneous Exercise Page No. 278

1. Three vertices of a parallelogram ABCD are A(3, -1, 2), B(1, 2, -4) and C(-1, 1, 2). Find the coordinates of the fourth vertex.

Solution:

Given:

ABCD is a parallelogram with vertices A (3, -1, 2), B (1, 2, -4), and C (-1, 1, 2).

Where, $x_1 = 3$, $y_1 = -1$, $z_1 = 2$;

$x_2 = 1$, $y_2 = 2$, $z_2 = -4$;

$x_3 = -1$, $y_3 = 1$, $z_3 = 2$

Let the coordinates of the fourth vertex be D (x, y, z).

We know that the diagonals of a parallelogram bisect each other, so the midpoints of AC and BD are equal, i.e., Midpoint of AC = Midpoint of BD(1)

Now, by the midpoint formula, we know that the coordinates of the mid-point of the line segment joining two points P (x_1 , y_1 , z_1) and Q (x_2 , y_2 , z_2) are $[(x_1+x_2)/2, (y_1+y_2)/2, (z_1+z_2)/2]$

So we have,

Co-ordinates of the midpoint of AC:

$$= \left(\frac{3-1}{2}, \frac{-1+1}{2}, \frac{2+2}{2} \right)$$

$$= (2/2, 0/2, 4/2)$$

$$= (1, 0, 2)$$

Co-ordinates of the midpoint of BD:

$$= \left(\frac{1+x}{2}, \frac{2+y}{2}, \frac{-4+z}{2} \right)$$

So, using (1), we have

$$\left(\frac{1+x}{2}, \frac{2+y}{2}, \frac{-4+z}{2} \right) = (1, 0, 2)$$

$$\frac{1+x}{2} = 1, \frac{2+y}{2} = 0, \frac{-4+z}{2} = 2$$

$$1+x=2, 2+y=0, -4+z=4$$

$$x=1, y=-2, z=8$$

Hence, the coordinates of the fourth vertex are D (1, -2, 8).

2. Find the lengths of the medians of the triangle with vertices A (0, 0, 6), B (0, 4, 0) and C (6, 0, 0).

Solution:

Given:

The vertices of the triangle are A (0, 0, 6), B (0, 4, 0) and C (6, 0, 0).

$$x_1 = 0, y_1 = 0, z_1 = 6;$$

$$x_2 = 0, y_2 = 4, z_2 = 0;$$

$$x_3 = 6, y_3 = 0, z_3 = 0$$

So, let the medians of this triangle be AD, BE and CF, corresponding to the vertices A, B and C, respectively.

D, E and F are the midpoints of the sides BC, AC and AB, respectively.

By the midpoint formula, the coordinates of the midpoint of the line segment joining two points P (x_1, y_1, z_1) and Q (x_2, y_2, z_2) are $[(x_1+x_2)/2, (y_1+y_2)/2, (z_1+z_2)/2]$

So, we have

The coordinates of D:

$$\begin{aligned} &= \left(\frac{0+6}{2}, \frac{4+0}{2}, \frac{0+0}{2} \right) = \left(\frac{6}{2}, \frac{4}{2}, \frac{0}{2} \right) \\ &= (3, 2, 0) \end{aligned}$$

The coordinates of E:

$$\begin{aligned} &= \left(\frac{0+6}{2}, \frac{0+0}{2}, \frac{6+0}{2} \right) = \left(\frac{6}{2}, \frac{0}{2}, \frac{6}{2} \right) \\ &= (3, 0, 3) \end{aligned}$$

And the coordinates of F:

$$\begin{aligned} &= \left(\frac{0+0}{2}, \frac{0+4}{2}, \frac{6+0}{2} \right) = \left(\frac{0}{2}, \frac{4}{2}, \frac{6}{2} \right) \\ &= (0, 2, 3) \end{aligned}$$

By the distance formula, the distance between two points P (x_1, y_1, z_1) and Q (x_2, y_2, z_2) is given by

$$PQ = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$$

So the lengths of the medians are:

$$\begin{aligned} AD &= \sqrt{(3 - 0)^2 + (2 - 0)^2 + (0 - 6)^2} = \sqrt{3^2 + 2^2 + (-6)^2} = \sqrt{9 + 4 + 36} \\ &= \sqrt{49} = 7 \end{aligned}$$

$$\begin{aligned} BE &= \sqrt{(3 - 0)^2 + (0 - 4)^2 + (3 - 0)^2} = \sqrt{3^2 + (-4)^2 + 3^2} = \sqrt{9 + 16 + 9} \\ &= \sqrt{34} \end{aligned}$$

$$\begin{aligned} CF &= \sqrt{(0 - 6)^2 + (2 - 0)^2 + (3 - 0)^2} = \sqrt{(-6)^2 + 2^2 + 3^2} = \sqrt{36 + 4 + 9} \\ &= \sqrt{49} = 7 \end{aligned}$$

\therefore The lengths of the medians of the given triangle are 7, $\sqrt{34}$ and 7.

3. If the origin is the centroid of the triangle PQR with vertices P ($2a, 2, 6$), Q ($-4, 3b, -10$) and R ($8, 14, 2c$), then find the values of a, b and c.

Solution:

Given:

The vertices of the triangle are P (2a, 2, 6), Q (-4, 3b, -10) and R (8, 14, 2c).

Where,

$$x_1 = 2a, y_1 = 2, z_1 = 6;$$

$$x_2 = -4, y_2 = 3b, z_2 = -10;$$

$$x_3 = 8, y_3 = 14, z_3 = 2c$$

We know that the coordinates of the centroid of the triangle, whose vertices are (x_1, y_1, z_1) , (x_2, y_2, z_2) and (x_3, y_3, z_3) , are $[(x_1+x_2+x_3)/3, (y_1+y_2+y_3)/3, (z_1+z_2+z_3)/3]$

So, the coordinates of the centroid of the triangle PQR are

$$\left(\frac{2a - 4 + 8}{3}, \frac{2 + 3b + 14}{3}, \frac{6 - 10 + 2c}{3} \right) = \left(\frac{2a + 4}{3}, \frac{3b + 16}{3}, \frac{2c - 4}{3} \right)$$

Now, it is given that the origin (0, 0, 0) is the centroid.

$$\text{So, we have } \left(\frac{2a+4}{3}, \frac{3b+16}{3}, \frac{2c-4}{3} \right) = (0, 0, 0)$$

$$\frac{2a+4}{3} = 0, \frac{3b+16}{3} = 0, \frac{2c-4}{3} = 0$$

$$2a + 4 = 0, 3b + 16 = 0, 2c - 4 = 0$$

$$a = -2, b = -16/3, c = 2$$

∴ The values of a, b and c are $a = -2$, $b = -16/3$, and $c = 2$.

4. Find the coordinates of a point on the y-axis, which are at a distance of $5\sqrt{2}$ from the point P (3, -2, 5).

Solution:

Let the point on the y-axis be A (0, y, 0).

Then, it is given that the distance between the points A (0, y, 0) and P (3, -2, 5) is $5\sqrt{2}$.

Now, by using the distance formula,

We know that the distance between two points P (x_1, y_1, z_1) and Q (x_2, y_2, z_2) is given by

$$\text{Distance of PQ} = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$$

So, the distance between the points A (0, y, 0) and P (3, -2, 5) is given by

$$\text{Distance of AP} = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$$

$$= \sqrt{(3-0)^2 + (-2-y)^2 + (5-0)^2}$$

$$= \sqrt{3^2 + (-2-y)^2 + 5^2}$$

$$= \sqrt{(-2-y)^2 + 9 + 25}$$

$$5\sqrt{2} = \sqrt{(-2-y)^2 + 34}$$

Squaring on both sides, we get

$$(-2-y)^2 + 34 = 25 \times 2$$

$$(-2-y)^2 = 50 - 34$$

$$4 + y^2 + (2 \times -2 \times -y) = 16$$

$$y^2 + 4y + 4 - 16 = 0$$

$$y^2 + 4y - 12 = 0$$

$$y^2 + 6y - 2y - 12 = 0$$

$$y(y + 6) - 2(y + 6) = 0$$

$$(y + 6)(y - 2) = 0$$

$$y = -6, y = 2$$

\therefore The points (0, 2, 0) and (0, -6, 0) are the required points on the y-axis.

5. A point R with x-coordinate 4 lies on the line segment joining the points P (2, -3, 4) and Q (8, 0, 10). Find the coordinates of the point R.

[Hint: Suppose R divides PQ in the ratio k:1. The coordinates of the point R are given by

$$\left(\frac{8k + 2}{k + 1}, \frac{-3}{k + 1}, \frac{10k + 4}{k + 1} \right)]$$

Solution:

Given:

The coordinates of the points are P (2, -3, 4) and Q (8, 0, 10).

$$x_1 = 2, y_1 = -3, z_1 = 4;$$

$$x_2 = 8, y_2 = 0, z_2 = 10$$

Let the coordinates of the required point be (4, y, z).

So, let the point R (4, y, z) divides the line segment joining the points P (2, -3, 4) and Q (8, 0, 10) in the ratio k:1.

By using the section formula,

We know that the coordinates of the point R, which divides the line segment joining two points P (x_1, y_1, z_1) and Q (x_2, y_2, z_2) internally in the ratio $m:n$, is given by:

$$\left(\frac{mx_2 + nx_1}{m+n}, \frac{my_2 + ny_1}{m+n}, \frac{mz_2 + nz_1}{m+n} \right)$$

So, the coordinates of the point R are given by

$$\left(\frac{8k+2}{k+1}, \frac{-3}{k+1}, \frac{10k+4}{k+1} \right)$$

So, we have

$$\left(\frac{8k+2}{k+1}, \frac{-3}{k+1}, \frac{10k+4}{k+1} \right) = (4, y, z)$$

$$\Rightarrow \frac{8k+2}{k+1} = 4$$

$$8k+2 = 4(k+1)$$

$$8k+2 = 4k+4$$

$$8k-4k = 4-2$$

$$4k = 2$$

$$k = 2/4$$

$$= 1/2$$

Now, let us substitute the values, and we get

$$\Rightarrow y = \frac{-3}{\frac{1}{2}+1} = \frac{-3}{\frac{3}{2}} = \frac{-3 \times 2}{3} = -2,$$

$$z = \frac{10\left(\frac{1}{2}\right)+4}{\frac{1}{2}+1} = \frac{5+4}{\frac{3}{2}} = \frac{9 \times 2}{3} = 3 \times 2$$

$$= 6$$

∴ The coordinates of the required point are (4, -2, 6).

6. If A and B be the points (3, 4, 5) and (-1, 3, -7), respectively, find the equation of the set of points P such that $PA^2 + PB^2 = k^2$, where k is a constant.

Solution:

Given:

Points A (3, 4, 5) and B (-1, 3, -7)

$$x_1 = 3, y_1 = 4, z_1 = 5;$$

$$x_2 = -1, y_2 = 3, z_2 = -7;$$

$$PA^2 + PB^2 = k^2 \dots\dots\dots(1)$$

Let the point be P (x, y, z).

Now, by using the distance formula,

We know that the distance between two points P (x_1, y_1, z_1) and Q (x_2, y_2, z_2) is given by

$$PQ = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2}$$

So,

$$PA = \sqrt{(3 - x)^2 + (4 - y)^2 + (5 - z)^2}$$

And

$$PB = \sqrt{(-1 - x)^2 + (3 - y)^2 + (-7 - z)^2}$$

Now, substituting these values in (1), we have

$$[(3 - x)^2 + (4 - y)^2 + (5 - z)^2] + [(-1 - x)^2 + (3 - y)^2 + (-7 - z)^2] = k^2$$

$$[(9 + x^2 - 6x) + (16 + y^2 - 8y) + (25 + z^2 - 10z)] + [(1 + x^2 + 2x) + (9 + y^2 - 6y) + (49 + z^2 + 14z)] = k^2$$

$$9 + x^2 - 6x + 16 + y^2 - 8y + 25 + z^2 - 10z + 1 + x^2 + 2x + 9 + y^2 - 6y + 49 + z^2 + 14z = k^2$$

$$2x^2 + 2y^2 + 2z^2 - 4x - 14y + 4z + 109 = k^2$$

$$2x^2 + 2y^2 + 2z^2 - 4x - 14y + 4z = k^2 - 109$$

$$2(x^2 + y^2 + z^2 - 2x - 7y + 2z) = k^2 - 109$$

$$(x^2 + y^2 + z^2 - 2x - 7y + 2z) = (k^2 - 109)/2$$

Hence, the required equation is $(x^2 + y^2 + z^2 - 2x - 7y + 2z) = (k^2 - 109)/2$.
